allowed out at the rate of one penny per day, or sixpence per week;
after which time, if not renewed, a *fine* of twopence per day will be
imposed. No Instrument can be renewed, if wanted by another.

XII.—All cases not provided for in these Rules shall be settled by
the Committee.

N.B.—Members are requested to be extremely careful in the use of the
Books, as many of them are not only valuable, but rare, which at no
distant day it may be difficult, as well as expensive, to replace.

PAPILIO RHAMNI.

BRIMSTONE BUTTERFLY.

LEPIDOPTERA.

GENERIC CHARACTER.

Antennæ clavated, or knobbed at the end. Wings, when at rest, erect. Fly by day.

SPECIFIC CHARACTER

AND

SYNONYMS.

Wings angulated, entire, pale yellow, with a brown spot near the center of each. Underside very pale yellow. Antennæ reddish.

PAPILIO RHAMNI. Alis integerrimis angulatis flavis, singulis puncto ferrugineo.—*Linn. Syst. Nat.* 2. 765. 106.
—*En. Sv.* 1042.

A 2

Papilio

Papilio præcox sulphurea sive flavo viridis, singulis alis macula ferruginea notatis.—*Raj. Inf.* 112. 4.

Sulz. Inf. tab. 13. fig. 84.

Roes. Inf. 3. tab. 46. fig. 1. 2. 3.

————— 4. tab. 26. fig. 1. 5.

Degeer Inf. 1. tab. 15. fig. 1. 10.

Esp. Pap. 1. tab. 4. fig. 4.

Schæff. Elem. tab. 94. fig. 7.

————— *Icon. tab.* 35. fig. 1. 3.

The Brimstone Butterfly is common in many places in the month of June in the Fly state. In the Caterpillar state it is seldom taken, and when in chrysalis it is generally concealed among the herbage, where it is almost impossible to be discovered. In this state, like all other species of the Butterfly tribe, it is suspended by the tail, but has such muscular strength, that if touched it can throw itself upright immediately, in the same manner as the Chrysalis of *Phalæna pentadactyla*. It feeds chiefly on buck-thorn, whence it has received the specific name *Rhamni*.

2

P L A T E CXLVI.

BOMBYLIUS MEDIUS.

DIPTERA.

Wings two.

GENERIC CHARACTER.

Trunk taper, very long, between two horizontal valves.

SPECIFIC CHARACTER

AND

SYNONYMS.

Thorax and body yellowish brown, white at the extremity. Wings with brown spots.

BOMBYLIUS MEDIUS: alis fusco punctatis corpore flavescente postice albo.—*Linn. Syst. Nat.* 2. 1009. 2. 1919.

BOMBYLIUS PUNCTATUS niger villis fulvis, alis fusco punctatis.—*De Geer. Inf.* 6. 269. 2. tab. 15. fig. 12.

Schæff. Elem. tab. 27. 1.

———— *Icon. tab.* 78. fig. 3.

Fab. Syst. Ent. 802. 2.

———— *Spec. Inf.* 2. 473.

The Bombylius genus is very concise. *Fabricius* in the *Species Insectorum* enumerates only nine species, of those five are found in Europe, major, medius, minor, ater and fuscus; the three former are natives of this country; the fourth is frequent in Germany, the last

last in Italy.—To these Fabricius has added a few species in his last work *Entomologia Systema*, which have not been described before, but they are all exotics.

The species figured in the annexed plate is not common. It lives on the nectareous juice of flowers. Is found in May.

F I G. III.

MUSCA HYPOLEON.

DIPTERA.

GENERIC CHARACTER.

A soft flexible trunk, with lateral lips at the end. No palpi.

SPECIFIC CHARACTER.

Eyes brown. Thorax black, margined with yellow. Abdomen black, with five yellow spots. Legs yellow.

Musca Hypoleon. *Lin. Syst. Nat.*

Stratiomys Hypoleon. *Fab. Mantissa. 2. p. 347. N° 63.*

This Insect was taken last August, flying among some rushes in Battersea meadows. The line at Fig. 2. denotes the natural size.

P L A T E CXLVII.

GRYLLUS GRYLLOTALPA.

MOLE CRICKET.

HEMIPTERA.

Shells or upper wings semi-crustaceous, not divided by a straight future, but incumbent on each other, beak curved down.

GENERIC CHARACTER.

Head maxillous, and with palpi. Antennæ filiform, or taper. Wings folded. Hind legs strong for leaping.

SPECIFIC CHARACTER

AND

SYNONYMS.

Dark brown. Antennæ filiform, long, small. Head long and small. Four short palpi. Corselet cylindrical, shells small, veined, wings long. Body hairy. Two small tails. Fore feet large, palmated.

GRYLLUS GRYLLOTALPA. *Linn. Syst. Nat.* 2. 693. 10.

Gryllus supra fuscus, subtus ferrugineo flavus, pedibus anticis latis, compressis denticulatis. *De Geer. Inf.* 3. 517. 2.

Acheta gryllotaipa: alis caudatis elytro longioribus, pedibus anticis palmatis. *Fab. Syst. Ent.* 279. 1.—
Sp. Inf. 1. 353. 91. 1.

Catesby Carol. 1. tab. 8.

Frisch. Inf. 11. tab. 5.

Seb. Mus. 4. t. 89. fig. 3. 4.

Sulz. Inf. tab. 9. fig. 59.

Roef. Inf. 2. *Gryll. tab.* 14. 15.

It is scarcely possible to find a more singular creature than the Mole Cricket. It lives in burrows which it forms about an inch or more below the surface of the ground. The female deposits a large bed of eggs about the size of small pease, rather of an oval form, and brownish colour. They are laid in a circular cavity, which is two or three inches wide, and near an inch in height. An aperture is made on one side, with an easy ascent to the surface of the ground, and is ingeniously covered at the top with loose earth. When the young larvæ are first hatched, they scarcely exceed the twelfth of an inch in length. They ascend through the opening, and subsist on the plants nearest their habitation, till their fore claws have acquired sufficient strength to burrow into the earth. In the larva state they nearly equal the perfect Insect in size, and resemble it in every respect, except that they have no wings. The shells appear first; this is the pupa state, and shortly after the membranous wings appear also. It makes very little use of its wings, as they are too weak to support its body long; and indeed it has not much occasion for them, as it lives in the same manner as the Mole, and, like it, is furnished with powerful claws, with which it can burrow through the ground to a very considerable distance.

This destructive creature is generally found in great numbers wherever they once deposit their eggs; for it is impossible to pursue and destroy them without doing much injury to the ground they infest. If they find a way into a kitchen-garden, they sometimes destroy whole beds of young plants in the space of one night; and this is not astonishing, when we consider that they seldom eat any part except the roots, which they nip very close, and consequently the other parts must perish. They seem particularly fond of Lettuces.

Fig. I. one of the fore claws.

P L A T E CXLVIII.

PHALÆNA POTATORIA.

DRINKER MOTH.

LEPIDOPTERA.

GENERIC CHARACTER.

Antennæ taper from the base. Wings in general deflexed when at rest. Fly by night.

BOMBYX.

Antennæ, male feathered, female, like a bristle.

SPECIFIC CHARACTER

AND

SYNONYMS.

Yellow brown. Wings slightly scalloped; on each of the upper wings an oblique line, and two white spots near the anterior margin. Female paler colour than the male.

PHALÆNA POTATORIA: alis reversis subdentatis flavis, striga fulva repandaque, punctis duobus albis.—*Syst. Ent.* 564. 28.

PHALÆNA maxima alis e fulvo flavicantibus. *Raj. Inf.* 143. 3.

Goed. Inf. 1. tab. 12.

Sepp. Inf. 4. 37. tab. 8.

Schæff. Icon. tab. 67. fig. 10. 11.

Wilk. pap. 27. tab. 3. b. 2.

The Caterpillars of this Insect feed on grafs, they are found in May, and the Moth appears about the middle of June.

The female differs in several respects from the male; it is of a buff colour, and is generally, though not always, larger. The chrysalis is black, and is enclosed in a strong yellowish case, as shewn in the plate.

P L A T E CXLIX.

ATTELABUS CURCULIONOIDES.

COLEOPTERA.

Wings two, covered by two shells, divided by a longitudinal future.

GENERIC CHARACTER.

Antennæ thicker towards the end. Head narrow behind. Four joints in each foot.

SPECIFIC CHARACTER

AND

SYNONYMS.

Shells and thorax red. Head black.

ATTELABUS CURCULIONOIDES: niger thorace elytrisque rubis.—

Lin. Syst. Nat. 2. 619. 3.

Rhinomacer niger thorace elytrisque rubris, proboscide longitudine capitis.—*Geof. Inf.* 1. 273. 10.

Curculio Nitens, *Paykull. Monogr.* 130. 122.

Schæff. Icon. tab. 56. fig. 7.

Sulz. Inf. tab. 4. fig. 12.

A pair of this very singular and rare species was taken on a young nut tree in Darent Wood, Dartford, early in May, 1795.

The remarkable structure of it's head deserves particular notice; it is shaped like a vase, and when the Insect is alive is protruded

far beyond the thorax by it's long slender neck. It has also a very bufy motion of it's head from the right to the left when it runs: we obferve a fimilar motion in many Insects; but as few have fuch a slender neck, it is feldom fo quick and repeated as in this.

The natural fize is given in the upper part of the plate, the magnified appearance of the head is fhewn below.

Phalæna Marginata. Klemann's. Insecten Geschichte, &c.

Burnberg, 1792. Vol. 2. pl. 7. fig. 6. 7. 8.

The

The Synonyms of this rare Insect have been more minutely collected, than is common in the descriptions of this work, as it has been generally considered an undescribed species. Mr. Crow, of Feverham, who has enriched the collections of several gentlemen in London, with many curious Insects, met with two or three specimens of this Moth, and among others sent one to Mr. Bentley, a collector in London, a few years since. I have to acknowledge being favoured with this Insect by LORD WILLIAM SEYMOUR; his Lordship met with it in Wiltshire.

Fabricius, in the *Species Insectorum*, has made a very considerable error; and which it is proper to notice in this place, "*Noctua Marginata*, native of America," and described from the Collection of Dr. Hunter, occurs in page 216. spec. 40; and again in page 230. spec. 108, "*Noctua Marginata*, a native of Europe," the present specimen. The former he has indeed changed to "*Noctua Marginella*" in his last work, *Entomologia Systematicæ*, but without the slightest notice of the first mistake, or any reference to the *Species Insectorum*.

It appears to be a native of Germany by the last work published by *Klemann*, though perhaps it is very rare in that country as it is given in a supplementary series of plates to his work, and his plates are but a supplement of the more rare Insects, not figured in *Roefel's* publications.

O R A N G E M O T H.

L E P I D O P T E R A.

P H A L Æ N A.

S P E C I F I C C H A R A C T E R.

Upper wings orange colour with spots, waves, and streaks of brown; several minute white spots along the anterior margin. Body and lower wings cream colour, with a pale wave in the middle of the latter.

This is certainly a non-descript. *T. Marham, Esq. Sec. L. S.* has described it in his manuscript notes under the specific name Auran-tiago.

The specimen from which the figures in the annexed plate are copied was found on an oak in Richmond Park, in June, 1793. The under-side as well as upper-side is shewn in the plate.

PLATE CLI.

FIG. I.

MUSCA BRASSICARIA.

CYLINDRICAL FLY.

DIPTERA.

Wings 2.

GENERIC CHARACTER.

A soft flexible Trunk, with lateral lips at the end. No Palpi.

SPECIFIC CHARACTER

AND

SYNONYMS.

Thorax greenish. Abdomen cylindrical; second and third Segment reddish yellow.

MUSCA BRASSICARIA: antennis fetariis nigra, abdomine cylindrico: segmento secundo tertioque rufis. *Fab. Spec. Inf.* 2. 36. 443.—*Syst. Ent.* 25. p. 88.—*Mant. Inf.* I. 2. 43. 345.—*Ent. Syst.* 4. 327. 63.

Musca cylindrica: Antennis fetariis pilosa cinereo nigra, abdomine cylindrico elongato medio rufo. *Degeer. Inf.* 6. n. 9. p. 30. *tab. I. fig. 12.*

Mouche cylindrique. Ibid.

Die Kohlsiege. *Panz. Faun. Inf. Germ.*

The Muscæ, if we follow the arrangement of Linnæus, form by far the most extensive of any genus (except Lepidoptera) we have at present any knowledge of. Fabricius enumerates in his last * Work no less than 202 Species, under the generic title *Musca* ; independent of these we find 122, under the head *Syrphus* ; 22 under *Rhagio*, and 25 under *Stratiomys*, all of which (with some exceptions) would make by Linnæan arrangement 349 species ; not to notice the Insects of the same tribe included under his generic appellations, *anthrax*, *bibio*, *nemotelus*, &c.

Musca Brassicaria is not uncommon in gardens in May and June. Sometimes found on Willows.

Fig. 1. One of the Antennæ magnified.

* *Syst. Ent.*

FIG. II.

APIS TUMULORUM.

SMALL, LONG HORNED BEE.

HYMENOPTERA.

Wings four, generally membranous. Tail of the female armed with a sting.

GENERIC CHARACTER.

Jaws, with a Trunk bent downwards. Antennæ elbowed in the middle. Wings plain. Body hairy. Abdomen connected by a pedicle.

SPECIFIC CHARACTER

AND

SYNONYMS.

Antennæ rather longer than the body. Entirely black, with greyish hairs. Jaws yellow.

APIS TUMULORUM. *Lin. Syst. Nat.* 2. 953. 2. edit. 3.—*Fn. Sv.* 1685.

Apis Tumulorum: Antennis filiformibus longitudine corporis nigri, maxillis flavis. *Fab. Syst. Ent.* 388. 57.—*Spec. Inf* 1. 486. 122.

Eucera Tumulorum, vol. 2. 344. 159.

Sulz. Hist. Inf. tab. 27. fig. 14.

This extraordinary Bee is found in Summer, against banks, when the weather is fine. Were it not for the remarkable length of the Antennæ, it would scarcely deserve notice, though it is rather a scarce Insect.

FIG. III.

TABANUS PLUVIALIS.

SPECKLED-WING. STINGING FLY.

DIPTERA.

Wings 2.

GENERIC CHARACTER.

Antennæ conic, of four Segments. Trunk fleshy, terminated by two lips. Palpi one on each side of the Trunk.

SPECIFIC CHARACTER

AND

SYNONYMS.

Eyes green. Thorax brown grey, with seven longitudinal lines. Abdomen grey with marks of black. Wings brown speckled with white.

TABANUS PLUVIALIS. *Lin. Syst. Nat.* 16. p. 1001. *edit.* 13. n. 16. p. 2885.—*Fn. Sv.* n. 1887.

Wood Leopard Moth. *Harris Inf. angl.*

It is to a very singular and trivial circumstance we are indebted for the specimens of both the male and female of this rare species. They were observed together on the bark of an elm tree in the Mall in St. James's Park, by some ignorant persons, who being terrified at their extraordinary appearance, attempted to destroy them, but a gentleman

gentleman who happened to pass by at the same instant, having either more curiosity or less apprehension of danger from touching them, took them up, and preserved them. We conclude they could have but just before come out of their chrysalides, the female being in a most perfect state, and the male equally fine, except that it had lost one of its upper wings.

We must claim the indulgence of the more scientific part of our readers for the minuteness with which we have detailed such trifling circumstances; it can indeed afford very little amusement to them, but, it may serve to remind many who are not in the habit of collecting Insects, that their occasional endeavours would be likely to extend the Science of Entomology; for it often happens that the most assiduous Naturalists are indebted to such persons for the rarest specimens their cabinets can boast.

The Moths were found late in June. On examining the crevices of some of the trees near the spot, we found a quantity of the eggs; they were rather of an oval form, and linked together like a chain, as shewn in the Plate; and having carefully preserved them in a branch of a plumb-tree * under the bark, we had the satisfaction to see some young Caterpillars produced in a few weeks. But either owing to the want of proper food or good management they all died soon after except two or three, and these never arrived at their full size. The Caterpillar from which the Figure in the annexed is copied, was found under the bark of one of the elm-trees in St. James's Park, but being disturbed, it never became a Pupa. The Caterpillar makes a case, of the dust of the wood which it gnaws, and cements together, and in this it lies concealed beneath the bark. The head of the Caterpillar is hard, and the first ring is furnished with a strong horny substance.

Harris, about twenty years ago, was so fortunate as to breed this Moth from the Caterpillar, and we are not acquainted with any

* I frequently find, when the Plant of an Insect is unknown, that they will live on the Plumb-tree, when they refuse other food.

similar instance since that time. In the Plates of Roefel, vol. 4, a Figure of the Caterpillar is given, but without either Pupa or Moth, so that were it not for the reference and authority of Linnæus, and since his time, of Fabricius, it would scarcely be known to what Insect it belonged. The eggs we have not found either figured or described, though they are so very singularly united together, and would certainly have been noticed by the ingenious Roefel if he had met with them.

The Antennæ of the female are setaceous, or like a bristle, but that part of the male is both singular and beautiful; it is elegantly feathered next the base, and terminates in a bristle, like the female.

Hybn. Beytr. 2. tab. 3. fig. L.

This is not an uncommon Moth in some places, yet we find no figure of it in any work on British Insects. In the work of Klemm, quoted in the Synonyms, a figure of it is given without the Larva; from this we may safely infer it is seldom found in that state, or that indefatigable writer would certainly have added it to his Plate.

It is supposed to feed on some plant of the *Euphorbia* genus, and hence the specific names *fuscata* and *unicolorata* have been abandoned.

The Moth was found late in May.

Purple Vanear? *Harris. Inf.*

The Larva of this rare and elegant Insect is wholly unknown to Collectors of British Insects. The Moths were formerly taken at the Chalk-pits, near Charton, in Kent, but either the brood has been destroyed, or the seasons so unfavourable, that few, if any, have been seen for several years. The Moth comes forth in May, and, like other species of the same tribe, fly very low, and always settle on the blades of grass, with their Wings folded, so that Collectors can readily distinguish them from other Moths.

P L A T E CLIV.

FIG. I, II, III.

SCARABÆUS NOBILIS.

SCARCE GREEN CHAFFER.

COLEOPTERA:

Wings two, covered by two shells, divided by a longitudinal future.

GENERIC CHARACTER.

Antennæ clavated, extremities fissile *. Five joints in each foot.

SPECIFIC CHARACTER

AND

SYNONYMS.

Shining green ; shells, full of wrinkles. Thorax not projecting.

SCARABÆUS NOBILIS: scutellatus muticus auratus, abdomine postice albo punctato. *Linn. Syst. Nat.* 2. 558. 81.—
Fn. Sv. 401.

abdomine postice albedine maculato, pectore
mutico. *Degeer. Inf.* 4. 297. 26.

* Divided into laminæ, or parts.

This species is not much unlike the *Scarabæus Auratus* (large green Beetle, or Rose Chaffer) but is far more scarce. The larva lives entirely under the surface of the ground, and feeds on smaller Insects. The Jaws are very strong, but in other respects it appears unable to defend itself if attacked. It is very sluggish, and always lies with its body coiled round. The case in which it remains in the pupa state is very strong, and consists of small bits of wood, pebbles, earth, &c. cemented and fastened together, by a slight silky web. It continues during the Winter in this case, and in May the Beetle comes forth.

———— *Icon. tab. 16. fig. 1.*

Le Colibri. *Harris. Aurel. pl. 24.*

There are two sorts of Caterpillars belonging to this species. They are alike in size and form, but are very different in colour. One sort is green, the other purplish red, varying much in different specimens, being sometimes almost brown. Both sorts are spotted with minute white specks, which are disposed in regular order over every part, except the belly.

Every Caterpillar is also furnished with a posterior horn, which is blue from the base for more than half its length : the tip is bright orange colour.

The Chrysalis, which is of a pale yellowish-brown at first, changes to a more dusky colour before the Sphinx comes forth.

The Caterpillars feed on several kinds of plants, but seem chiefly to prefer those of the *Galium* genus, particularly, the White * or Yellow † Lady's Bedstraw, and Cleaves, or Goosegrafs ‡. They go into the ground about the latter end of August, and remain there in chrysalis till April, or May at the farthest.

It is rather a scarce Insect : sometimes visits gardens in the winged state ; and extracts the sweetest juices of the flowers, by darting its long proboscis, or trunk into them ; it is from this peculiarity, and its hovering over the flowers at the same time, like the Humming Birds when they feed, that it has received its English appellation.

* *Galium Palustre.*

† ——— *Verum.*

‡ ——— *Aperine.*

This Insect is found in most parts of Europe, but it appears is more frequent in Northern Countries. A near variety of it is found in Botany-Bay ; and we have specimens of it from North America.

Sphinx Belis of Linnæus and Cramer, is described amongst the Synonyms given by Fabricius, as a variety of *Sphinx Stellatarum*, and *Sphinx Ciculus* of Cramer scarcely differs from our Insect.

Der Bergmannische Nachtfalter. *Langs Verz.* p. 203. n. 1379, &c.

Linnaeus gave this little Moth the specific name *Bergmanniana*, in honour of Prof. Bergmann, a naturalist of distinguished eminence. It is a very pretty Insect; but, when magnified, its appearance is truly superb, the ground colour which is bright yellow, shewing the orange markings to great advantage, and the metallic splendour of the burnished silver appearing like raised work above the stripes or bands of dark brown that cross the upper wings.

We have found this Moth at Highgate. The Caterpillars are yellow, with a streak of green down the back; but the green disappears before the last skin, in which they are of a pale yellow, without any marks whatever. They feed on white thorn.

This

This extremely rare Insect is always considered as a British species, and is usually found in the cabinet of the English entomologist; yet those are German Insects generally, for we know only of one specimen which is clearly ascertained to have been found in this country. The specimen alluded to is in the collection of Mr. Francillon, jeweller, in Newcastle-street, in the Strand: it is a female, and was found by that gentleman's brother in his garden at Carlhalton.

Whether Harris ever met with this Insect we cannot pretend to determine; he says it appears in the winged state in April*. We cannot hesitate to suppose, that this Moth has been found in England several times, particularly in *Kent*; but none of these remain at this period in the collections of the curious.

The Male differs much from the Female: both sexes are shewn in the annexed plate. Fig. I. Male. Fig. II. Female.

Fuesly, in a German publication, has given the only figure we are acquainted with of the Caterpillar of this Moth; and *Fabricius* has copied his description from the coloured engraving. It is green, with oblique lines of yellowish brown, and large spots of golden yellow.

This species is less frequent than *Oniscus Afellus*, (Common Woodlouse). It lives in clear waters, most part of the summer. It

G

scarcely

scarcely exceeds one half of the length of *O. Afellus* in England, yet if we may form an opinion of the German specimens from those figured by *Sulz*, they are larger than with us.

The *Oniscus Agilis* of *Perfoon*, figured in Panzer's Work *, corresponds perfectly with ours in size ; and the minute markings on the shells, if carefully examined with a glass, will be found nearly alike. The antennæ of the figure in *Sulz* seems rather contrary to the specific character of the insect ; and that of Panzer's, though of another species, more resemble those of our specimen.

Of the *Oniscus Afellus* we find different coloured specimens, some are almost white with grey marks, others are nearly deep black ; we find also, *Oniscus Aquaticus* liable to variations, though not so much as the former insect in some the light ground colour is very distinct, in others rather confused. Some are deeper coloured ; and again, many, when first taken, have a fine glowing, olive brown appearance throughout, though less vivid than that of *Oniscus Agilis* before noticed.

The light Tussock Moth is found late in September, or during the month of October. The Caterpillar is both beautiful and singular: it feeds on the oak, on which it is met with, from the latter end of July till the middle of September, at which time it is of its full size, and becomes a pupa; it spins a web between the leaves, and remains in the chrysalis about thirty days. The eggs are of a pale brownish colour, fig. 1.

Lin. Syst. Nat. 2. 665. 8.—*Fn. Sv.* 772.

The transformation of any insect from one state to another is both curious and entertaining to an enlightened observer ; yet there are a few species whose manners are so peculiar, and their changes so astonishing, that they seem to demand more than ordinary attention ; and of this description we consider the subject of the annexed plate. If we speak of it as to its manners collectively, one peculiarity implies a contradiction of the other, for it is an aquatic, a terrestrial, and an aerial creature. Few insects that inhabit the water, in the perfect state ever quit it ; and the generality of those whose larvæ live in that element could exist for a few minutes only in it, after they become winged insects ; this is particularly noticed of the *Libellulæ*, *Phryganææ*, *Ephemeræ*, *Tipulæ*, and an immense croud of other insects that are bred in the water ; but it appears this insect in the larva state can leave the water without injury, and in the last state, though a winged creature, it lives for the most part in the water, and quits it only in the evenings ; or when the pool dries up, it uses its wings in search of another.

In the larva state it is not less remarkable for its savage disposition, than its formidable appearance. The whole body is covered with a hard shell, or coat of mail, and the head is armed with two long, semi-circular, sharp-pointed forceps. It is very alert in the water, and when it takes its prey, which consists of smaller aquatic insects, it plunges these weapons into them, and through a minute aperture, at the extremity, it extracts all their juices. When the time arrives in which it is to become a pupa, it leaves the water and forms a cavity just below the surface of the earth of an oval form : how long it remains in this cavity in the pupa state is uncertain. The beetle comes forth in May.

Much doubt has arose respecting the female of this species ; Linnæus, in the *Systema Naturæ*, described the supposed female as *β Dyfficus Semisfriatus*. Fabricius, in the *Species Insectorum*, adds a long list of synonyms from different entomological writers, several of whom had figured or described it as a distinct species before the time of Linnæus, and some subsequent authors have held the same opinion ; but in the last work, *Entomologia Systema*, Fabricius considers it to be the

the female, and includes only a few of his former references. Upon the first view of these opinions the point seems undetermined; and though we partly assent to the opinion of the last writer, we must endeavour to be entirely satisfied, before we give a figure of *Dytiscus Semistriatus*.

The upper side of this insect is generally described black; this is not the colour in living specimens: it is of a fine glossy black-green, and the marginal colour brighter than in those that have been dead some time. The greenish hue on the back seldom entirely disappears.

The fore feet of this beetle have an appendage of a very singular structure; it is nearly round, flat beneath, and has in the middle two remarkable circular cavities, with many others more minute: it is supposed, that through minute apertures in these cavities it can emit a kind of oily fluid; or that, by their assistance, it can collect air bubbles, to raise itself from the deep parts of the water to the surface, in an instant. The larva of the *Musca Chamælion*, which lives in the water, collects the air in a bubble within the rays of its tail, and thereby raises itself to the surface in like manner.

That the *Phalæna Dispar* was not uncommonly scarce about fifteen years ago, is evident from this circumstance, few collections of British insects, that were in the hands of eminent collectors, are without an English specimen, which was procured about that time; and Harris, in 1775, as well as some other writers about the same period, speak confidently of its being found in this country. Berkenhout, in his Synopsis, says, it is “*frequent* about Ealing, in Middlesex.” But this we can, on the best authority, dispute; it never was frequent in that place, though it has several times been met with, by collectors of insects; a parcel of eggs being obtained from them, and hatching, many caterpillars were procured; and these being carefully attended, several moths were also produced. This is not a very extraordinary circumstance, as many of the rarest insects may become common, when the eggs, or a brood of caterpillars, can be discovered.

We are willing to acknowledge, that we have not been more fortunate in our researches for the caterpillar or moth of this species, than any others engaged in the science of entomology; but we have procured from Germany a collection, containing many valuable rarities that have been found in this country at different times; amongst these we have most perfect and finely preserved specimens of *Phalæna Dispar*, in its several states, and these perfectly agree with those formerly collected in England. Our Plate contains only one figure of the caterpillar, and that is of the female. The male differs only in being smaller, and in the size of the head, which is less in proportion than that of the female.

In this instance, we trust, any apology will be unnecessary, though the original specimens were not found in this country: it must be an advantage to the work to contain figures of the rarest insects; and should any of our readers be so fortunate as to find the caterpillar, they will be able to determine the species, and the proper food to rear it on; or, if the brood be extinct, the plate will be more interesting, as there cannot remain a doubt of its having been indigenous in England.

In foreign countries it is very injurious to gardens, and fruit-trees in particular. *Berkenhout* says, it feeds on “Oak, Ash, Apple-trees, &c.” but we are rather inclined to doubt his information, except as to the latter, though he is partly sanctioned by *Linnaeus*. *Geoffroy* says, it feeds on the Elm.

For the time of its appearance we are indebted to *Harris*; he says the caterpillar changed to chrysalis the 11th of July, the moth appeared July 31; from which it appears certain that he reared it from the caterpillar. He has not, however, given a figure of it in the *Aurelian*, or any other of his publications.

Scop. carn. 722.

Reaum. Inf. 5. tab. 14. fig. 10. 12.

In the larva state, this species feeds on the leaves of the Rose, and from that peculiarity it has received its significant specific name, *rosæ*. The larva casts its skin several times before it becomes a pupa, its exuviae we frequently find adhering to rose-leaves. When the larva is in its last skin it is yellowish, inclining to orange, with many minute black specks, disposed in ringlets, on every joint; but in the early stages of its growth we find them of several shades of colours, between green and orange, and some partake of both colours, and are speckled with black, as in the last skin. The larva is very tender, and, we suspect, is liable to some distemper of a very different kind from any noticed to affect other insects; it then appears sickly, and is covered with a whitish down, or powder, which flies off on the slightest touch. We have often found the larva of another species of the same genus covered with this kind of white powder, but as they always died, it is impossible to determine to what insect they belonged.

In the pupa state, the outer case is not perfectly oval, but rather flattened on the sides; it is generally fastened on a stalk. The perfect insect is found in great plenty during most of the summer months.

Several early systematic writers placed this insect amongst those whose antennae consisted of seven joints, or articulations: Whence *Linnaeus* * included the number of the joints with the specific cha-

* In the last edition of the *Syst. Nat.* "*antennis septemnodis, &c.*" is changed for "*antennis clavato filiformibus, &c.*"

rafter ; and in the Species Insectorum *Fabricius* has followed the same arrangement. Though with the assistance of a microscope we may discover in this, and other species, the exact number of the articulations described, yet they are too minute to serve as part of a good specific character, which should, if possible, be selected from the most conspicuous and peculiar parts of the insect. *Fabricius* seems to have been aware of this in his last work, *Entomologia Systematica**; and has made a very judicious alteration ; though it appears singular for a systematic writer to change “ *Antennis filiformibus articulis 7—9.*” for “ *Antennis inarticulatis, extrorsum crassioribus.*”

The

The caterpillar of this species is found on the White Thorn, in April ; in May it becomes a pupa : the moth does not appear before September.

It will be readily conjectured, from its English name, to be more frequently taken about *Ealing*, in *Middlesex*, than elsewhere, though it is not peculiar, like some insects, to one place only. The caterpillar is smooth, or without any hairs ; it eats ravenously, is very sluggish, and forms a fine silky web, in the ground, in which it passes to the pupa state *. We find the moth very liable to variation in colours ; in some specimens the green is very brilliant, in others the red ; and again, in others, the lunar white marks are very conspicuous. In some specimens, natives of warm countries, we have seen them finer coloured than those from the northern parts of Europe.

* In the plate of this species in Roel's German Insects, the silky cone of the pupa is drawn in the convex part of a leaf,

If we except a very small number of exotic *Libellulæ*, *L. Grandis* is the largest insect of the genus known: it is certainly the largest of the European species.

It is not uncommon in woods; but never flies far from the water. In the larva state it lives in the water, and, like others of the same genus already described in this work, does not quit it till it becomes a winged creature. In the larva state it also resembles in its manners those voracious insects that devour smaller insects, and in the winged state it takes moths and other weak insects in its flight. Is found in most of the summer months.

* Like a necklace of small beads.

The Staphylini were formerly known among English collectors by the general appellation *Rove-Beetles*; we have in the present instance adopted this English name, and added the only specific distinction which occurs likely to convey the meaning of Linnæus, when he named it *Riparius*.

All the insects of this genus are very voracious. The larvæ so much resemble the perfect insects, that they can hardly be distinguished from them. *Staphylinus Riparius* is found in most parts of Europe. It frequents moist sandy places, and the sides of banks. Found in May. The natural size and magnified appearance is given in the annexed plate.

Wien Verz. 103. 1.

Insects, when in the larva state, have various means of protecting, or concealing themselves from other species that would annoy them, as well as from birds who prey on them. This remark is partly justified by the subject of our annexed plate, the larva of which we find is not furnished with any means of defence when attacked: nor of agility to run away, or secrete itself from its enemies; but to compensate for this, nature has formed it with a skin of such a colour, and structure, that its greatest safety is in its inaction. We frequently see it fastened by its hind feet to a small twig or branch in such a posture, that unless it moves, it is scarcely possible to discover it. It is sometimes in an erect position, at others with its head downwards, but in an oblique position; and, as it hangs in this manner, without the least appearance of life for a considerable time, it exactly resembles a small twig of the branch to which it is attached.

The caterpillars are not uncommon in April, or early in May. It feeds on several plants; particularly, when in confinement, it prefers bramble, or white thorn. It is found in the winged state in June, so that it remains a very short time in chrysalis.

O F

PHALÆNA FRAXINI.

The rarity of this subject must plead our apology for the liberty we have taken in introducing it into our work. It is the only instance in which we have given place to a copy from the works of others of any subject, however rare. We have in our possession a preserved specimen of the caterpillar of *Phalæna Fraxini*, sent from Germany; but as it is of that kind in which the colours and form cannot be preserved well, we have preferred giving an exact copy of the caterpillar as well as chrysalis, from the works of a respectable, but little known author, *Ammiral*. This author appears to have been singularly fortunate in presenting a figure of the caterpillar, when the accurate Roefel did not publish a figure of the moth till his fourth volume, and was not then in possession of the caterpillar.

Some of our readers will be perhaps surpris'd to find that our figures precisely agree with those contained in the Aurelian of our countryman *Harris*; but whoever possesses the plates of *Ammiral*, will find that in the most minute parts of *Harris's* plates, he has only traced and reversed the originals of *Ammiral* throughout; and in many instances by a clumsy imitation, in reversing the foliage and flies, has even spoilt the effect, and lost sight of the accuracy of them.

A specimen of this very superb and rare butterfly has been taken at Cambridge. It has always had a place in the cabinets of English collectors of consequence; but we cannot learn by whom it was first discovered in this country. *Papilia Virgaureæ* and *Papilio Hippothoe*, have been frequently confounded with each other; but on a comparison, a material difference will be discovered.

Harris has made one error, which it is of importance to the English collector to correct; he says, “*Papilio Virgaureæ*, copper, feeds on grass, found in June and August in meadows, is shining copper, spotted with black.” From this it appears he could mean no other than the common copper butterfly, which is found in June and August in meadows, *Papilio Phlæas*; for though the scarce copper butterfly was probably found in his time, it must have been very rare;

rare; and he would not have omitted in his catalogue of English Lepidopteræ, to mention an insect so common as *Papilio Phlæas*, if he had noticed the other. He has also the same error in his Aurelian.

LEPIDOPTERA.

GENERIC CHARACTER.

Antennæ taper from the base. Wings in general deflexed when at rest. Fly by night.

Bombyx.

Antennæ of the male feathered.

SPECIFIC CHARACTER

AND

SYNONYMS.

First wings grey, speckled with brown: a broad space of brown across each, and a triangular white spot near the anterior margin.

The Pine Lappet Moth is one of the species
can have no doubt are natives of this country

testimony of the respectable authors; though from the scarcity of many amongst them, we should be scarcely inclined to admit them into an English collection without such authority. Perhaps the rarity of some of those insects should be rather attributed to the little attention bestowed on the science of Entomology by such as reside in parts of the kingdom that are most favourable to the increase of insects in general; or to those particularly rare species that are local, or feed only on plants of one kind; such as the *Sphinx Euphorbiæ*, and many others.

Wilks has given the Pine Lappet Moth in the third plate of the English butterflies. *Harris* has not figured it in the Aurelian*, but in the Pocket Companion† he not only describes it amongst the English Lepidoptera, but says, the time of its changing into Chrysalis is *May*, and that it appears in the winged state in June; from this we must suppose, that he had reared it from the Caterpillar. *Berkenhout*, in his synopsis of the natural history of Great Britain‡, has given it without hesitation as an English insect; and the authority of a little tract on insects, by Martin§, may be adduced as a further confirmation of its being a native of this country.

This Insect is not uncommon in Germany. Schæffer has figured amongst the insects that are to be found in the environs of Raand Roefel, without considering it a local species, has as a native of Germany. Whether it is found in other parts except Switzerland and Germany, we cannot decide; it is a new species from *Georgia* in *North America*.

Considerable difference between the colouring of this species of *Schæffer* and *Roefel*, which is the more remarkable as both describe the insects of the same country; the former is much darker in the chestnut colour, and has the appearance of an intermixture of red specks and white as figured in *Schæffer*, which inclines very much to the former throughout. *Roefel* has only figured the female; both sexes.

Musca maxima crabroniformis. *Raj.* 1.

Erax crabroniformis. *Scop. carn.* 974.
Schaeffer. Icon
— *Elea*

This is a very confined genus. Fabricius in the *Species Insectorum* describes only thirty-three kinds; of these not more than eight are natives of this country. The *Afilus Crabroniformis* is the largest, and is not uncommon in some places in the summer, particularly frequenting wet meadows, and flying busily about the middle of the day amongst flowers.

Its proboscis is a curious instrument; the sting of it is very painful, and causes a swelling.
